

AN OPEN INITIATIVE BY KARMALAB

Unbias AI

Building a broader picture.

AI is learning how to picture us.

Generative image models now take part in how humans are pictured in everyday life, in ad campaigns, education materials, media, entertainment, and online communication.

prompt: *"create a portrait of a person"*

15 times using OpenAI's gpt-image-2 model

But this picture is not neutral.

Ask a model for something that sounds neutral and the same faces, bodies and settings tend to come back.

In the majority of cases, results are identical in race, gender and age.

SAME PROMPT. 100 GENERATIONS.

■ identical profile

■ one dimension changed

■ more than one dimension changed

a doctor

a CEO

a teacher

a beautiful person

a family

a person at home

Models learn from what we give them.

Models learn visual patterns from enormous collections of images. Where those collections are uneven, the patterns come back out.

What a model has seen a lot of,
it creates more of.

What it has rarely seen becomes
even rarer.

What if we could correct this bias?

Open-source image models can be adapted after they have been trained. Using a **smaller, carefully constructed dataset**, we can teach a model additional visual patterns without rebuilding it from scratch.

This technique is called a **LoRA**: a lightweight adaptation that changes how a model generates images while leaving the original model intact.

Measure the bias → correct it
→ measure again

What if we could do it together?

Training datasets normally sit **out of sight**.

We want to create a **training dataset** that people can see, join and question.

visible

collective

consented

open to anyone

Anyone can contribute.

People contribute their own photos, or photos of people who gave permission. Each image is reviewed manually by a real person.

01

Upload

A photo you took, or one you have permission to share.

02

Identify people

The interface finds the people in the photo and suggests the labels.

03

Describe representation

The contributor confirms or corrects every label themselves.

04

Consent

Nothing is stored until the contributor gives explicit consent.

05

Human review

A moderator reviews every image before it joins the dataset.

The dataset grows in public.

Online

A live dashboard shows how close each representation target is.

On people's phones

Visitors scan a code and contribute images where they stand.

In cultural spaces

A large interactive installation shows the dataset growing as people contribute.

Numbers are updated in real time when people add photos to the dataset.

Our first goal: 10,000 people.

An image dataset built by the public,
with clear targets for each bias.

5 bias dimensions

6,482 / 10,000

A person reviews every contribution
before it joins the approved dataset.
Targets describe coverage, not an ideal
population.

AGE — FIVE EQUAL TARGETS

GENDER

SKIN TONE — MONK SCALE 1-10

BODY

VISIBLE DISABILITY / ASSISTIVE DEVICES

Each model gets its own correction.

01

Measure

Check how existing open-source image models represent people, using a transparent evaluation tool.

02

Correct

Make a selection of images from the collective dataset designed to correct the specific biases of each model.

03

Train

Train corrective LoRAs and methods for specific open-source models.

04

Measure again

Test whether representation actually improved, and publish what we find.

Built open source and transparent.

The ambition is not just the dataset. It is
a method other people can pick up,
repeat and argue with.

Started by KarmaLab. Built for others to join.

All applications and code is open source under the MIT license.
Available on github.com/karmalab-tech

Access to the dataset stays
controlled. Research or training
access is discussed case by case.
